Name - Gyan Bahadur Gurung

This report is an addendum to a long original sonic wave technology report written by me (Gyan Bahadur Gurung). Here in this report, I have attempted to describe sonic wave photo technology, sonic wave video technology, and sonic wave memory technology in more detail. Sonic wave photo technology is a technology I received first hand in February of 2021. Photo technology has the following features. People can think of an object and they see the object they think in different positions around a head and a body. Those objects can be any photo or a short video or it can be a recorded thought of a person. A recorded thought can be seen inside of a head or even in the air. One person can think of something and another person can see recorded thoughts inside of his or her head or even in the air. A person who is set up to stay inside of the head of another person can smell after which that person inside of whom another person is smelling can see different photos, videos or thoughts. Also, one person can think and another person can see objects that the first person thinks.

Sonic wave video technology is also a technology I received first hand in February of 2021. This technology allows people to send videos from computer software to the human brain. Human brains see those videos in their brain. This technology is usually used to show dreams to people while they are sleeping. While showing dreams to a person, different things are to be considered. A video can be edited to make sure how it wants to be shown to a person's brain. In order to see what a person to whom a dream is being shown is seeing in his or her brain, you have to use ID software to set up all connected people to see from that person's eyes to whom a dream is being shown. A sensation object can be kept inside of any person. This will help sense another person's sensations. The speed of display of a video in a person's brain can be configured with computer software. A thought can be transferred to a person's brain to whom a dream is being shown. A counter thought of that certain thought can be transferred to that person to whom a dream is being shown. Sexual sensation and counter sexual sensation can be sent to a person's body to whom a dream is being shown. A sexual sensation will generate a feeling to have sexual intercourse and a counter sexual sensation will generate a feeling to not have sexual intercourse. A sexual release sensation can be sent to a person's body to whom a dream is being shown. This will make a person leak sexual release. A counter sexual release sensation can be sent to a person to whom a sexual release sensation has been sent, which will prevent leaking sexual release. A heat or cold sensation can be sent to a person's body to whom a dream is being shown. An ejaculation sensation and a counter ejaculation sensation can be sent to a person to whom a dream is being shown. An ejaculation sensation passes sperm or ova and a counter ejaculation sensation stops passing sperm or ova. A souvenir object can be set up as well to listen to the thoughts of any person.

Sonic wave memory technology is also a technology I received first hand in February of 2021. A memory technology is a sonic wave technology which extracts

information or data from a human brain memory. There are two ways to extract human brain memory. One way is by using advanced devices and computer probes to extract memory information or data to create a memory data file. Another way is by using sonic waves remotely. Sonic waves can remotely extract memory data and create a memory data file. In both cases, a person whose memory data is to be extracted must be sleeping and not moving. There are different things that need to be considered in sonic wave memory technology. A small section of a memory data can be sent to a person's brain to figure out what that memory data is about. It is a memory replay in another person's brain. That memory doesn't have any date. You have to ask people when that memory has developed and put that date in a memory data file. The memory replay has to be done for a small section of a human brain memory data file; otherwise, a memory replay is difficult to detect in a memory data file. A section of memory data can be very short depending on how a person thinks. Some people think very short while other people think longer than other people. If a memory data replay reveals a very short thought and it is difficult to figure out what that memory is by memory replay, you have to ask people about that memory data. Then, a longer thought that reveals that very short thought can be created by another person and that longer thought can be inserted in a memory data file. A fake memory data can also be created. A fake thought can be created by a person and that thought can be inserted in another person's memory data file. Later, if another person replays that memory in a person’s brain memory, that person might think that that memory is real, but in reality that memory is fake. A person's past brain memory data can only be detected by replaying that memory data in a person's brain. If a given memory data is very fast and replaying that memory in a person's brain is difficult to read because that memory is very fast, memory replay has to be done for a longer time by increasing the time length of that section of memory data. In this way, a person's life history can be known with an extraction of that person's brain memory data, a creation of a human brain memory data file, and replaying that memory data in any person's brain.

This part is about the use of a very small camera in sonic wave technologies. A small camera can be used to record a person's body posture and gesture. Based on that person's body posture and gesture, different things can be done to a person such as dropping an object, fart, smell sensation, pee sensation or poof sensation. A given body posture or gesture that is recorded in a satellite system can drop an object in a person’s body, send a fart sensation to a person, send a smell sensation to a person, send a pee sensation to a person, and send a poof sensation to a person. On the receiving end, sensations sent from the satellite system can make a person fart, make a person smell something, make a person have a pee sensation, or make a person have a poof sensation.

Here in this report, I want to note that there are about eighty five commands that sonic wave technologies have developed. There are about eighty five activities that take

place in a human brain and body and that sonic wave technologies have built. For every activity that takes place in a human brain and body, information is encoded and is received in a brain. Encoded information is picked up by sonic waves and is sent to a satellite where programming source code reads this unique information. For every unique encoded information, a unique command is sent to the satellite system from where back ups of encoded information on the earth are created and from where encoded information is sent to people whose sonic IDs are connected to the person whose encoded information is picked up by sonic waves. On the receiving end, people receive that unique encoded information and know about that unique encoded information. In this way, one person can know activities taking place in another person's brain. So far about eighty five activities that take place in a human brain can be known by other people whose IDs are connected to the person where activities are taking place. If a satellite is to receive encoded information from a person's brain via sonic waves and sends it directly to all people on the earth at a given time, all people on the earth will know that encoded information. Luckily, sonic wave technologies allow only people whose IDs are connected to the person's sonic ID to read the encoded information in their brain.

How is it possible to send encoded information only to connected IDs? Each person's ID is unique. When a sonic wave ID of a person is created, that person's brain is taken into account. Each person's brain is unique. Based on the unique nature of a person's brain, a unique ID of that person is created. A unique ID is an object but it represents unique encoding of a person's brain. That is why, encoded information sent to one ID can't be read by another person's ID or brain.

I have also contributed a first project idea to the development of sonic wave technologies. This technology project receives encoded information from a human brain through sonic waves and a satellite transmits that information directly to all people on the earth, not just to people whose IDs are connected to the person whose brain’s encoded information is transferred to the satellite. For example, a person says something and all people on the earth are able to listen to that person. In a similar manner, all encoded information from a person's brain can be known by all people on the earth at a given time. Encoded information is received at a satellite from a human brain and is processed by some Java programming language source code after which C++ programming language source code in the satellite hardware is used to transmit that encoded information to all people on the earth. This is just a feasible project idea. This project is not yet developed.

I have also contributed another second project idea in developments of sonic wave technologies. Actually, sonic wave IDs are connected by using ID software. Information is sent from ID software to a server on the earth from where that information is sent to a satellite where sonic wave IDs are connected. In this way sonic wave IDs of people are connected to each other. After IDs of people are connected, sonic wave

technologies work on the fact that information from a person's brain is picked up by sonic waves and is sent to the satellite from where that information is sent to connected people. People on the receiving end receive that information in their brain and that is how a person or more than one person is capable of knowing information occurring in another person's brain. My project idea is information received at the satellite from a person's brain can be sent to a computer and from this computer we know that information taking place in a person's brain. My project idea works in different sonic wave technologies in the following ways.

1. Whatever a person sees in his or her brain can be sent to the satellite from where it is sent to a computer and people are able to see that information in that computer. That is how a person can see whatever another person is seeing on a computer.
2. Voices of people can be sent to the satellite from where these voices are sent to a computer and people are then able to listen to those voices from the computer. It would be amazing to listen to those voices from a headphone or small chip inserted in a head near an ear.
3. Thoughts of a person can be sent to the satellite from where these thoughts can be sent to a computer and from this computer these thoughts can be sent to people's brain. People will receive these thoughts in their brain and know what another person is thinking.
4. Head or body sensations of a person can be sent to the satellite from where these sensations can be sent to a computer and from this computer these sensations can be sent to people who will then receive these sensations in their brain and know about those sensations taking place in a head or body of another person.

There are other things that need to be added to a long sonic wave report written by me. These things are the following.

1. In sonic wave seeing eye technology or akha technology, you can make a person see bright light inside of his or her closed eyes and on the outer surface of his or her closed eyes in two ways. Bright light can be recorded by passing bright light to a person's closed eyes. You can send this recorded sensation to a person's brain whose eyes are closed after which that person sees bright light either inside of his or her closed eyes or on the outer surface of his or her closed eyes. A very short video that has bright light can also be sent to a person's brain whose eyes are closed. After receiving bright light in his or her brain, that person sees that bright light either inside of his or her closed eyes or on the outer space of his or her closed eyes.
2. In sonic wave sensation technology, anti sensations of all sensations of a human head or body can be recorded and can be used in a person's head or body at a later time.

3. In sonic wave sensation technology, a sensation of dropping down tears from a person's eyes can be recorded and used at a later time.
4. In sonic wave sensation technology, a sensation that makes a person difficult to see can be recorded and used at a later time.
5. In sonic wave akha technology or seeing eye technology, there is a data file which contains recorded data of a person's sight. You can send these data to a person's brain to replay what an original person has seen. In this way a recorded sight data file can be used with using a special ID software.
6. In sonic wave souvenir technology, a person can see live thoughts of a person's thinking. For example, if a person is talking on a person's sonic wave ID, that person's thoughts can be seen just before that person starts to talk or when that person is talking. These thoughts can be seen by a person on whose sonic wave ID other people are talking.
7. In sonic wave voice technology, while people are talking on a person's sonic wave ID, that person's sonic wave ID can be known by using sonic wave ID software.
8. In sonic wave technologies, ID bags can be deleted and recovered by using sonic wave ID software.
9. In sonic wave technologies, the history of a sonic wave ID can be known by using sonic wave ID software. In other words, all records of sonic wave IDs that are connected to a sonic wave ID can be known by using sonic wave ID software.
10. In sonic wave technologies, some brain activities that are recorded in the past can be replayed. Sonic wave technologies such as sonic wave ID voice technology, sonic wave souvenir technology, sonic wave memory technology, sonic wave akha or seeing eye technology and sonic wave sensation technology can be replayed at a later time. Sonic wave voice technology can record people's voices and those voices can be replayed in a computer or in a person's brain for detection at a later time. Sonic wave souvenir technology can record people's thoughts and those thoughts can be replayed in a person's brain for detection at a later time. Sonic wave memory technology can extract human memory data and that memory can be replayed in a person's brain for detection at a later time. Sonic wave akha or seeing eye technology can record what people see and that sight can be replayed in a person's brain for detection at a later time. And finally, sonic wave sensation technology can record what people sense in their head or body and those sensations can be replayed in a person's brain for detection at a later time.
