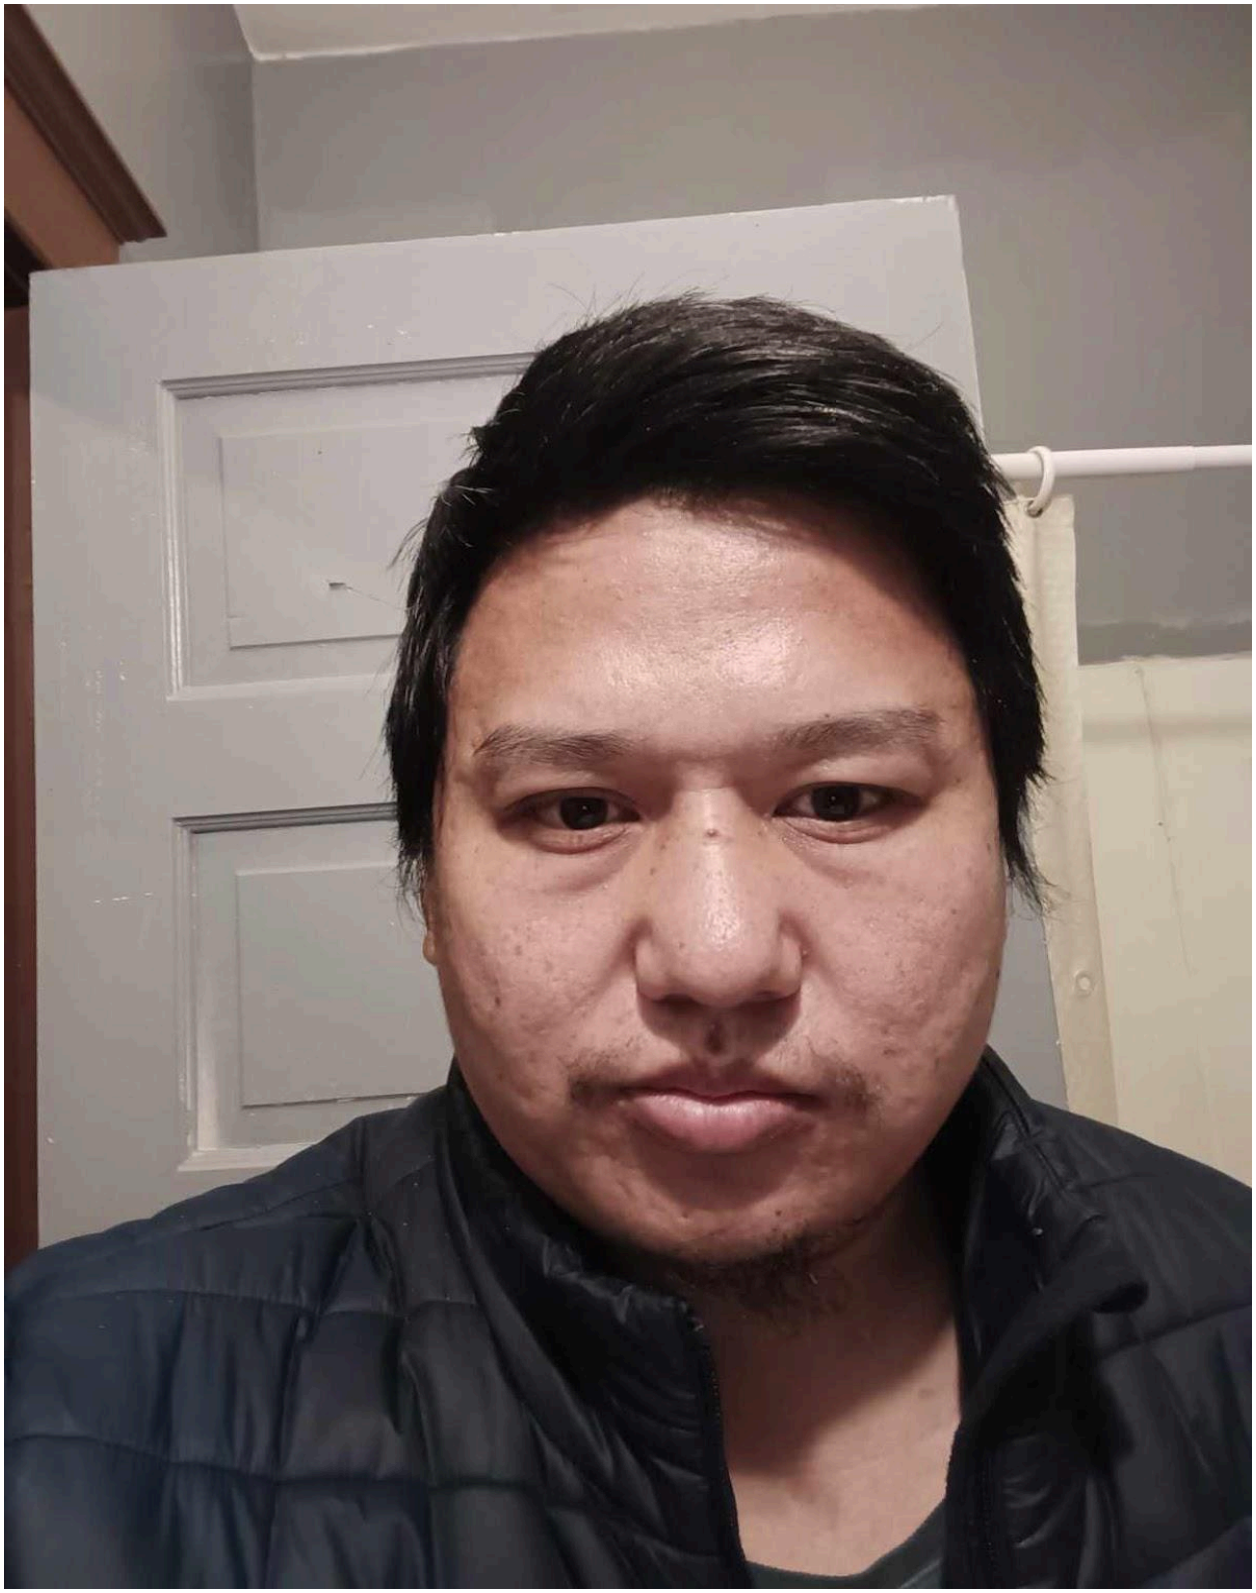
Name - Gyan Bahadur Gurung



A radio wave is a big thing. Radio waves are used for different purposes. Cell phone towers use radio waves. Satellite networks use radio waves. TVs, radios, vehicle radios, and FMs also use radio waves. There is a type of radio wave that, if used abusively, can paralyze a person's brain and body. RFID stands for radio frequency identifier detection. RFID technology uses radio waves for tracking. RFID technology is used to track money and count money from a stack of money if money is not older than four years. In other words, if money is older than four years, money can't be tracked. Debit cards and credit cards use RFID technology for tracking. Decks of cards and chips in casinos use RFID technology for tracking. Casino card games use RFID technology for detection and tracking. Poker games use RFID chips in cards to detect cards. Texas hold'em is a type of poker game that uses RFID chips in cards to detect cards. After a deck of cards is shuffled, cards of each player can be known before dealing cards to players. Not only that, a winner in that hand can be known without first dealing. That is how accurately RFID chips are used in cards in Texas hold'em.

Sonic wave technology is a pretty big and wonderful technology. Sonic waves are derived from radio waves. In 1993, Arizona University in the U.S. built labs for studying and researching sonic wave technology in rats. A command with the help of sonic waves was given to rats to perform some activities such as eating and the rats ate. In 2000, the U.S. international army figured out human brains emit waves to a certain distance and this can be combined with sonic wave technology to study and research the human brain. Animals also emit waves from their brains to communicate with each other. In a similar manner, human brains also emit waves. The U.S. international army started out developing sonic wave technologies in 2000. The then President Bill Clinton didn't know about these two developments. This project was picked up by Arizona University in 2004. At that time the then President George W. Bush knew little about this development. People from China were hired. They along with experts from the U.S. started out building sonic wave technologies that work with human brains. The U.S. was pretty good at developing details about this sonic wave technology. When they were going in the wrong direction, the Chinese were there to help move forward in the right direction.

Arizona University and Massachusetts Institute of Technology (MIT) have developed eight sonic wave technologies. These eight sonic wave technologies are sonic wave voice technology, sonic wave souvenir technology, sonic wave small scale object technology, sonic wave photo technology, sonic wave video technology, sonic wave memory technology, sonic wave akha or seeing eye technology or eye technology, and sonic wave sensation technology. In order for these technologies to work, sonic wave IDs of people have to be connected with each other. Sonic wave IDs are small scale objects made up of plastic, they are antimatter. People use sonic wave ID software to create sonic wave IDs of people. When a sonic wave ID of a person is being created, that person shouldn't be moving. When a person's sonic wave ID is created, a

small plastic object is created and placed in that person's head or body. After sonic wave IDs of people are created by using sonic wave ID software, a unique number is assigned to each sonic wave ID. People use these unique numbers in sonic wave ID software to reference sonic wave IDs made up of plastic which are present in people's head or body. How are sonic wave IDs of two or more people connected with each other? People use sonic wave ID software to connect the unique sonic wave ID number of one person with the unique sonic wave ID number of another person. Once they are connected in sonic wave ID software, information is sent from sonic wave ID software to a server on the earth from where that information is sent to a satellite. In the satellite one or more sonic wave IDs are connected with each other and the satellite sends that information to the human brains whose sonic wave IDs are to be connected with each other. After that, sonic wave ID small plastic objects are sent to the satellite from one or more people whose sonic wave IDs are to be connected with each other and from the satellite they are sent to a person on whom one or more sonic wave IDs are to be connected. When people do that, sonic wave ID small plastic objects are collected in a person's head or body. In this way, people use sonic wave ID software to create sonic wave IDs of people, people use sonic wave ID software to connect sonic wave IDs of one or more people, the satellite connects two or more sonic wave IDs with each other, and sonic wave ID small plastic objects of one or more people are transferred from one or more persons to a person on whom one or more sonic wave IDs are to be connected.

There are many different features of these eight sonic wave technologies, but I have attempted to describe these technologies in a short way in this short report. Detailed descriptions of these technologies and descriptions of features of these technologies are available in my long report. Short descriptions of these technologies are the following.

1. Sonic wave voice technology - This technology was developed by Arizona University in 2008. With this technology, people can remotely communicate with each other without using any technological devices. As long as there is a satellite reach, people can talk with each other by using this sonic wave voice technology. In order to remotely communicate with other people, sonic wave IDs of people have to be connected with each other. People use sonic wave ID software to connect one or more sonic wave IDs with a sonic wave ID. How is it done? After sonic wave IDs of one or more people are connected to a sonic wave ID in sonic wave ID software, information is transferred from a user computer ID software to a server on the earth from where that information is sent to the satellite. It is in the satellite where two or more sonic wave IDs are connected with each other. Then the satellite transfers one or more sonic wave ID small plastic objects from one or more people to a person's head or body on whom one or more sonic wave IDs are to be connected. In this way, sonic wave IDs of one or more people are connected to a person's sonic wave ID. After one or more sonic wave IDs are

connected with a person's sonic wave ID, these people can communicate with each other without using any technological devices. A person can talk. When he or she talks, that voice information is processed in his or her brain after which that listens what he or she is talking and that voice information is transferred to a satellite by sonic wave. From the satellite that voice information is transferred to one or more people's brains. In this way, voice information transfer takes from a person's brain to one or more people's brain. This is a brain to brain voice information transfer. After that one or more people can hear a remote person talking. In this way one or more people can communicate with each other.

2. Sonic wave souvenir technology - This technology was developed by Arizona University in 2008. By using this technology, one or more people can know a person's thoughts. If a person is thinking, one or more people can use this technology to read or know what that person is thinking. In order to read another person's thoughts, sonic wave IDs of one or more people have to be connected to that person whose thoughts are to be read and people should use sonic wave ID software to configure to read that person's thoughts. How are sonic wave IDs of one or more people connected to a person's sonic wave ID? People use sonic wave ID software to connect sonic wave IDs of one or more people to that person's sonic wave ID whose thoughts are to be read. After that, information is sent from a user computer to a server on the earth from where that information is sent to a satellite. It is in the satellite that sonic wave IDs are connected to each other. Then the satellite transfers sonic wave ID small plastic objects of one or more people to that person's head or body whose thoughts are to be read. In this way, sonic wave IDs are connected to each other. Since one or more people's sonic wave IDs are configured to listen to a person's thoughts, people can know what that person is thinking. That person thinks in his or her brain and sonic waves transfer those thoughts to the satellite from where those thoughts are sent to one or more people's sonic wave IDs or brains. This is how thought information is sent from one person's brain to one or more people's brains. On the receiving end, people receive thoughts in their brains and know about those thoughts taking place in another person's brain. This is how one or more people can know what a person is thinking by using sonic wave souvenir technology.
3. Sonic wave small scale object technology - This technology was developed by Arizona University in 2010. This technology uses micro scaled small objects made up of plastic. These small objects are antimatter. These small objects pass through house roofs and skin, flesh, organs and bones of a person. People use sonic wave ID software to connect their sonic wave IDs with a person's sonic wave ID. How are sonic wave IDs of these people connected to that person's sonic wave ID? People use sonic wave ID software to connect their sonic wave IDs with a person's sonic wave ID. After that, that information is sent from a user

computer to a server on the earth from where that information is sent to a satellite. It is in the satellite that the sonic wave IDs of these people are connected to that person’s sonic wave ID. Then the satellite transfers sonic wave ID small plastic objects of these people to that person’s head or body. In this way, people connect their sonic wave IDs to that person’s sonic wave ID. After that, these people use sonic wave ID software to insert and spin small plastic objects in different parts of that person’s head or body. These small plastic objects can be spinned in any direction and can be moved in any direction in the air and in different parts of that person’s head or body. In this way people use sonic wave ID software to use small plastic objects in different parts of a person’s head or body.

How does the use of small plastic objects in different parts of a person’s head or body work? People use sonic wave ID software to use small plastic objects in the software. That information from a user computer is sent to a server on the earth from where that information is sent to the server where small plastic objects are created. These objects are then sent to the satellite from where these objects are sent to a person’s head or body or the space around his or her body. Then, people use small plastic objects in sonic wave ID software and as a result, these objects are used in the air around that person’s position and in different parts of the head and body of that person. In this way, people use sonic wave ID software to use small plastic objects on a person’s sonic wave ID.

It is not that people only use manufactured small plastic objects, people can reuse these objects too. Small objects to be reused are stored on different people's sonic wave IDs. People can reuse these stored small plastic objects. How is it done? People have to first transfer these small plastic objects to a person's sonic wave ID from a stored sonic wave ID by using sonic wave ID software. Then they connect their sonic wave IDs to that person’s sonic wave ID on whom these small plastic objects are intended to use. After that, they use these small plastic objects in sonic wave ID software and as a result, these small plastic objects are used in the air above and around that person’s head and body and also in different locations of that person’s head and body. In this way, small plastic objects are reused.

These small plastic objects are recycled too. After small plastic objects are used on a person’s sonic wave ID, these objects can be recycled too. How is it done? People use sonic wave ID software to recycle unwanted small plastic objects. People use sonic wave ID software to transfer these small plastic objects to a location on the earth where these micro scaled plastic objects are recycled. These unwanted small plastic objects are melted and are used to create new micro scaled small plastic objects. In this way, unwanted micro scaled plastic objects are recycled.

4. Sonic wave photo technology - Our late father, Chandra Bahadur Gurung, received sonic wave photo technology firsthand in 2020. Arizona University has developed this technology. A photo is first edited to make sure how it wants to be displayed on a person's sonic wave ID. Then, people use sonic wave ID software to send that photo to a person's sonic wave ID. After that photo is sent from ID software it is received in a server on the earth from where it is sent to a satellite. From the satellite that photo is sent to the selected ID. A sonic wave ID is selected by using sonic wave ID software. A selected ID then receives this photo. When I write this I mean a human brain receives that photo. After that, a person sees that photo in the space above his or her head, in his or her head, inside of his or her body, or in the space around his or her body. In this way, a photo is sent from ID software and finally that photo is seen by a person whose sonic wave ID is selected by using sonic wave ID software.
5. Sonic wave video technology - Our late father, Chandra Bahadur Gurung, received sonic wave video technology firsthand in 2020. Arizona University has developed this technology. In this technology a video is sent from ID software to a person's ID or brain. After that that person sees that video in his or her brain. This display of video in a person's brain can be done when a person is awake and as well as when a person is sleeping. When a person is sleeping and a video is shown to him or her in his or her brain, that person who is sleeping sees a dream. This technology is basically used to show dreams to a person when he or she is sleeping. In this technology a video is first edited to make sure how it wants to be shown to a person. The speed of display of a video can also be set up. Then using sonic wave ID software that video is sent to a server on the earth from an end user computer ID software and from the server that video is sent to a satellite from where it is sent to a selected ID. A sonic wave ID is selected by using sonic wave ID software. A selected ID or a person's brain receives that video in his or her brain and sees it in the brain. If a person is sleeping, that person sees that video in the brain and sees a dream.
6. Sonic wave memory technology - I received this sonic wave memory technology firsthand in February of 2021. Arizona University has developed this technology. A memory technology is a sonic wave technology which extracts information or data from a human brain memory. There are two ways to extract human brain memory. One way is by using advanced devices and computer probes to extract memory information or data to create a memory data file. Another way is by using a special sonic wave remotely. Sonic waves can remotely extract memory data and can create a memory data file. In both cases, a person whose memory data is to be extracted must be sleeping and not moving. There are different things that need to be considered in sonic wave memory technology. A small section of a memory data can be sent to a person's brain to figure out what that

memory data is about. It is a memory replay in another person's brain. That memory doesn't have any date. You have to ask people when that memory has developed and put that date in a memory data file. The memory replay has to be done for a small section of a human brain memory data file; otherwise, a memory replay is difficult to detect in a person's brain. A section of memory data can be very short depending on how a person thinks. Some people think very short while other people think longer than other people. If a memory data replay reveals a very short thought and it is difficult to figure out what that memory is by memory replay, you have to ask people about that memory data. Then, a longer thought that reveals that very short thought can be created by another person and that longer thought can be inserted in a memory data file. A fake memory data can also be created. A fake thought can be created by a person and that thought can be inserted in another person's memory data file. Later, if another person replays that memory in a person's brain memory, that person might think that that memory is real, but in reality that memory is fake. A person's past brain memory data can only be detected by replaying that memory data in a person's brain. If a given memory data is very fast and replaying that memory in a person's brain is difficult to read because that memory is very fast, memory replay has to be done for a longer time by increasing the time length of that section of memory data. In this way, a person's life history can be known with an extraction of that person's brain memory data, a creation of a human brain memory data file, and replaying that memory data in any person's brain.

7. Sonic wave akha or seeing eye technology or eye technology - I received this sonic wave seeing eye technology (also known as akha technology or eye technology) firsthand in March of 2021. Massachusett Institute of Technology (MIT) has developed this technology. Seeing eye technology is a technology that is used to see from another person's eyes. By using this technology, you can remotely see what another person is seeing. In order to see from another person's eyes, sonic wave IDs of people have to be connected to that person's sonic wave ID and people use sonic wave ID software to configure for these people to see from that person's eyes. After people use sonic wave ID software to connect different sonic wave IDs to connect with that person's sonic wave ID, that information is sent from sonic wave ID software to a server on the earth from where it is sent to a satellite. The satellite finally connects different sonic wave IDs of these people with that person's sonic wave ID. Then the satellite transfers sonic wave ID small plastic objects of these different people to that person's head or body. In this way, sonic wave IDs of different people are connected with each other. When that person sees a view in front of him or her, images are formed in his or her eye retinas and that person's brain processes that view after which that person is capable of seeing that view in front of him or her. Then that view

information is picked up by sonic waves and is sent to a satellite from where it is sent to connected IDs or different people's brains. In this way, sight information is sent from one person's brain to another person's brain. This is how brain to brain information transfer takes place. Once people receive information in their brain they are capable of seeing things from another person's eyes. As long as there is a satellite network outreach these people can remotely see what that person is seeing.

8. Sonic wave sensation technology - I received this sonic wave sensation technology firsthand in March of 2021. Massachusett Institute of Technology (MIT) has developed this technology. By using this technology one or more people are capable of sensing another person's sensations such as cut sensation, pain sensation, sneezing sensation, poof sensation, pee sensation, and other sensations. First, sonic wave IDs of different people have to be connected with each other by using sonic wave ID software. People use sonic wave ID software to connect sonic wave IDs of different people with each other. That information from ID software is sent to a server on the earth from where that information is sent to a satellite. It is in the satellite where different IDs are connected with each other. Then the satellite transfers one or more sonic wave ID small plastic objects from one or more people to a person's head or body. In this way, sonic wave IDs of different people are connected with each other. That person where sonic wave ID small plastic objects are collected feels something and that sensation is received in his or her brain after which the brain knows that sensation after which that person is capable of knowing that sensation. That sensation information from that person's brain is picked by sonic waves and is sent to a satellite from where it is sent to connected IDs or brains of different people. This is a brain to brain sensation information transfer. People's brains receive this sensation after which they are capable of knowing sensation taking place in that person's head or body. If one or more people want to know sensations taking place in another person's head or body, a comb shaped sensation object, that is in the shape of a men's hair cutting device comb object, has to be placed in that person's body where that sensation is taking place and sonic wave IDs of these people have to be connected with each other by using sonic wave ID software.
